Overview

Today's Materials

Regression Models for Count Outcomes

- Poisson Regression model
- Negative Binomial Regression model
- Zero-inflated models
 - ZIP (Zero-inflated Poisson)
 - ZINB (Zero-inflated Neg. Binomial)
- Hurdle models
- Tobit (censored) regression models

```
medicare <- read.csv("medicare.csv") %>% tbl_df
```

Today's Goal

Predict visits using some combination of these 6 predictors...

Predictor	Description
hospital	number of hospital stays
health	self-perceived health status (poor, average, excellent)
chronic	number of chronic conditions
sex	male or female
school	number of years of education
insurance	is the subject (also) covered by private insurance? (yes or no)

Model 1: A Poisson Regression

Poisson Regression

Assume our count data (visits) follows a Poisson distribution with a mean conditional on our predictors.

Store Predictions

```
1 5 5.658592 -0.6585917
2 1 5.961186 -4.9611865
```

Calculating a Pseudo-R² for mod_1

```
(mod_1_r <- with(mod_1_aug, cor(visits, .fitted)))
[1] 0.3144637
(mod_1_r^2)</pre>
```

[1] 0.09888744

glance(mod 1)

Summarizing the Model's Fit

```
null.deviance df.null logLik AIC BIC
1 26942.92 4405 -17971.61 35959.23 36010.35
deviance df.residual
1 23167.81 4398
```

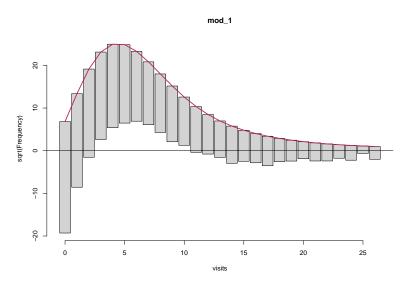

Building a Rootogram

To build a rootogram, you need to load the countreg package. This package is housed on R-Forge, rather than CRAN, so you need to install it with . . .

in order to use it.

Rootogram: See the Fit (using default choices)

countreg::rootogram(mod_1)

Interpreting the Hanging Rootogram

- The red curved line is the theoretical Poisson fit.
- "Hanging" from each point on the red line is a bar, the height of which represents the difference between expected and observed counts.
 - A bar hanging below 0 indicates that the model under-predicts that value. (Model predicts fewer values than the data show.)
 - A bar hanging above 0 indicates over-prediction of that value. (Model predicts more values than the data show.)
- The counts have been transformed with a square root transformation to prevent smaller counts from getting obscured and overwhelmed by larger counts.

How many zero counts does Model 1 predict?

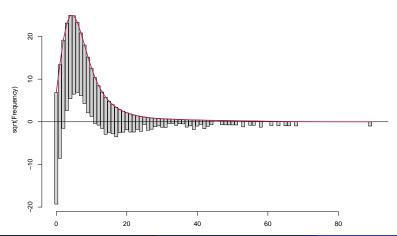

```
lam <- predict(mod_1, type = "response") # exp. mean count
exp <- sum(dpois(x = 0, lambda = lam)) # sum the prob(0)
round(exp)</pre>
```

[1] 47

How many subjects with zero visits did we see?

The Complete Hanging Rootogram for Model 1

Rootogram for Poisson mod_1

Interpreting the Rootogram for Model 1

In mod_1, we see a great deal of underfitting for counts of 0 and 1, then overfitting for visit counts in the 3-10 range, with some underfitting again at more than a dozen or so visits.

• Our Poisson model (mod_1) doesn't fit enough zeros or ones, and fits too many 3-12 values, then not enough of the higher values.

Do we have an overdispersion problem?

overdispersion ratio is 6.706136

p value of overdispersion test: 0

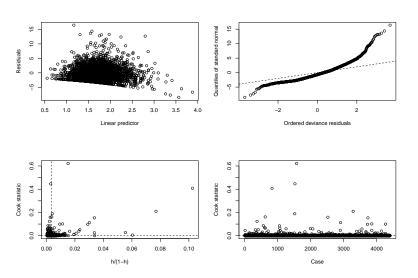

Dealing with Overdispersion?

To address the overdispersion, we'll adopt a negative binomial approach, in part because the rootogram tool we're using doesn't handle the quasipoisson model.

Code used on previous slide

```
yhat <- predict(mod_1, type = "response")
n <- 4406; k <- 8 # use display(mod_1) to see these
z <- (mod_1_aug$visits - mod_1_aug$.fitted) /
        sqrt(mod_1_aug$.fitted)
cat("overdispersion ratio is ", sum(z^2)/ (n - k), "\n")
cat("p value of overdispersion test: ",
        pchisq(sum(z^2)/(n-k), n-k), "\n")</pre>
```

glm.diag.plots from boot for Model 1

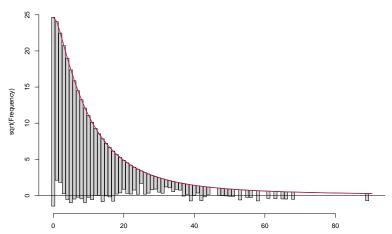

Model 2: A Negative Binomial Model

Fitting the Negative Binomial Model

Looks like our data are overdispersed compared to what a Poisson model expects.

Rootogram for Negative Binomial Model

Save predicted values and residuals

```
# A tibble: 2 x 3
  visits fitted resid
  <int> <dbl> <dbl>
1     5     5.79 -0.787
2     1     5.88 -4.88
```

Pseudo-R² for Neg. Bin. model (mod_2)

We can calculate a proxy for R^2 as the squared correlation of the fitted values and the observed values.

```
mod2_r <- with(mod_2_aug, cor(visits, fitted))
mod2_r^2</pre>
```

```
[1] 0.08271151
```

So Far ...

Model	Pseudo-R ²	Rootogram?	Comments
Poisson	0.099	• •	Data appear overdispersed.
Neg. Bin.	0.083		Still not enough zeros.

Model 3: Zero-Inflated Poisson (ZIP) Model

Zero-Inflated Poisson (ZIP) model

The zero-inflated Poisson or (ZIP) model is used to describe count data with an excess of zero counts.

The model posits that there are two processes involved:

- a logit model is used to predict excess zeros
- while a Poisson model is used to predict the counts

The pscl package is used to fit these zero-inflated models.

The Fitted Equation (part 1 of 2)

The form of the model equation for a zero-inflated Poisson regression requires us to take two separate models into account.

First, we have a logistic regression model to predict the log odds of zero visits. . .

That takes care of the extra zeros.

Zero-inflation model coefficients in mod_3

```

The Fitted Equation (part 2 of 2)

The form of the model equation for a zero-inflated Poisson regression requires us to take two separate models into account.

Second, we have a Poisson regression model to predict log(visits)...

```
log(visits) = 1.41 + 0.16 hospital -
     0.30 health = excellent + 0.25 health = poor +
     0.10 chronic - 0.06 sex = male + 0.02 school +
     0.08 insurance = yes
```

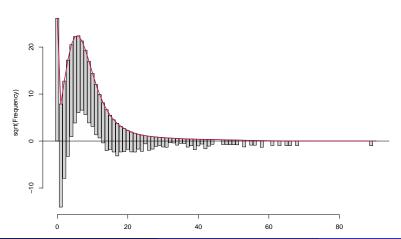

This may produce some additional zero count estimates.

So Far ...

Model	Pseudo-R ²	Rootogram?	Comments
Poisson	0.099	Many problems.	Data appear overdispersed.
Neg. Bin.	0.083	Better.	Still not enough zeros.
ZIP	0.107	All but 0 a problem.	Not enough 1-3.
ZINB	0.096	Better.	Zeros not a perfect fit.

Model 5: The Hurdle Model (Poisson)

The Hurdle Model

The hurdle model is a two-part model that specifies one process for zero counts and another process for positive counts. The idea is that positive counts occur once a threshold is crossed, or put another way, a hurdle is cleared. If the hurdle is not cleared, then we have a count of 0.

- The first part of the model is typically a binary logistic regression model. This models whether an observation takes a positive count or not.
- The second part of the model is usually a truncated Poisson or Negative Binomial model. Truncated means we're only fitting positive counts, and not zeros.

In fitting a hurdle model to our [medicare] data, the interpretation would be that one process governs whether a patient visits a doctor or not, and another process governs how many visits are made.

Fitting a Hurdle Model / Poisson-Logistic

Model 7: The Tobit (Censored Regression) Model

The Tobit (Censored Regression) Model

The idea of the tobit model (sometimes called a censored regression model) is to estimate associations for outcomes where we can see either left-censoring (censoring from below) or right-censoring (censoring from above.)

- Here, we might think of a broader latent (unobserved) variable that describes good health.
- We have censoring from below (at 0) where a person with good health (or better) has value 0.
- All of the people with better-than-good health take the same value (0) for visits.

The tobit model postulates that the value 0 in our model is just the lower limit of the underlying measure of poor physical health that we would actually observe in the population if we had a stronger measure.

Fitting the Tobit Model (uses VGAM::vglm)

Summary of Model 7

Fitted Equation

Using the type.fitted = "censored" approach, we'll get predictions limited to visit counts of 0 and larger. If the model below yields predicted visits < 0, we will fit 0. The model equation is:

Tobit model regression coefficients are interpreted as we would a set of OLS coefficients, except that the linear effect is on the **uncensored latent variable**, rather than on the observed outcome.

Save Fitted Values and Residuals
